**A 65 year-old woman was admitted to our hospital, because of unconsciousness after chest and back pain. Echocardiography showed pericardial effusion. She suffered from pre-shock due to cardiac tamponade.**

**Although a cause of cardiac tamponade was unclear, we performed emergency surgical treatment without coronary angiography. In operation, we found a rupture of coronary arteriovenous fistula and repaired it. The patient recovered from the surgery uneventfully.**

**Coronary artery fistula is an abnormal communication between a coronary artery and a cardiac chamber or major vessel. It is the most common congenital anomalies of the coronary arteries. Many patients with these anomalies remain asymptomatic, but some patients develop symptoms of congestive heart failure, infective endocarditis, myocardial ischemia, arrhythmia, or rupture of an aneurysmal fistula. Usually, the dilatation of fistula is common, and although 19% of this may become aneurysmal, the rupture of the aneurysm is very rare.**

**We report a case of ruptured coronary arteriovenous fistula who underwent successful emergent surgery. (Ann Thorac Cardiovasc Surg 2005; 11: 190–3)**

**Key words:** coronary arteriovenous fistula, cardiac tamponade, coronary aneurysm

### Introduction

A coronary artery fistula is the most common congenital anomaly of the coronary arteries and is an abnormal communication between an epicardial coronary artery and a cardiac chamber or major vessel. Although some patients develop symptoms of congenital heart failure, infective endocarditis, myocardial ischemia, arrhythmia, or rupture of an aneurysmal fistula, many patients with these anomalies remain asymptomatic. Rupture of an aneurysmal fistula is a very rare. We report here a case of ruptured coronary fistula who became unconscious after chest

and back pain. This patient developed cardiac tamponade and emergent surgical treatment was successfully performed.

### Case Report

A 65 year-old woman was admitted to intensive care unit in our hospital, because of unconsciousness after chest and back pain. Her past medical history includes hypertension and hyperlipidemia. On arrival, her consciousness was clear and she did not feel pain, but she was pre-shock. Her blood pressure was 76/40 mmHg and pulse rate was 90/min. A dilated neck vein was observed. Echocardiography performed on admission showed pericardial effusion and cardiac tamponade. Electrocardiograph (ECG) was normal sinus rhythm and indicated no change of ST-T wave. Computerized tomography (CT) showed no dissection of aorta, only pericardial effusion (Fig. 1). All other laboratory tests were normal.

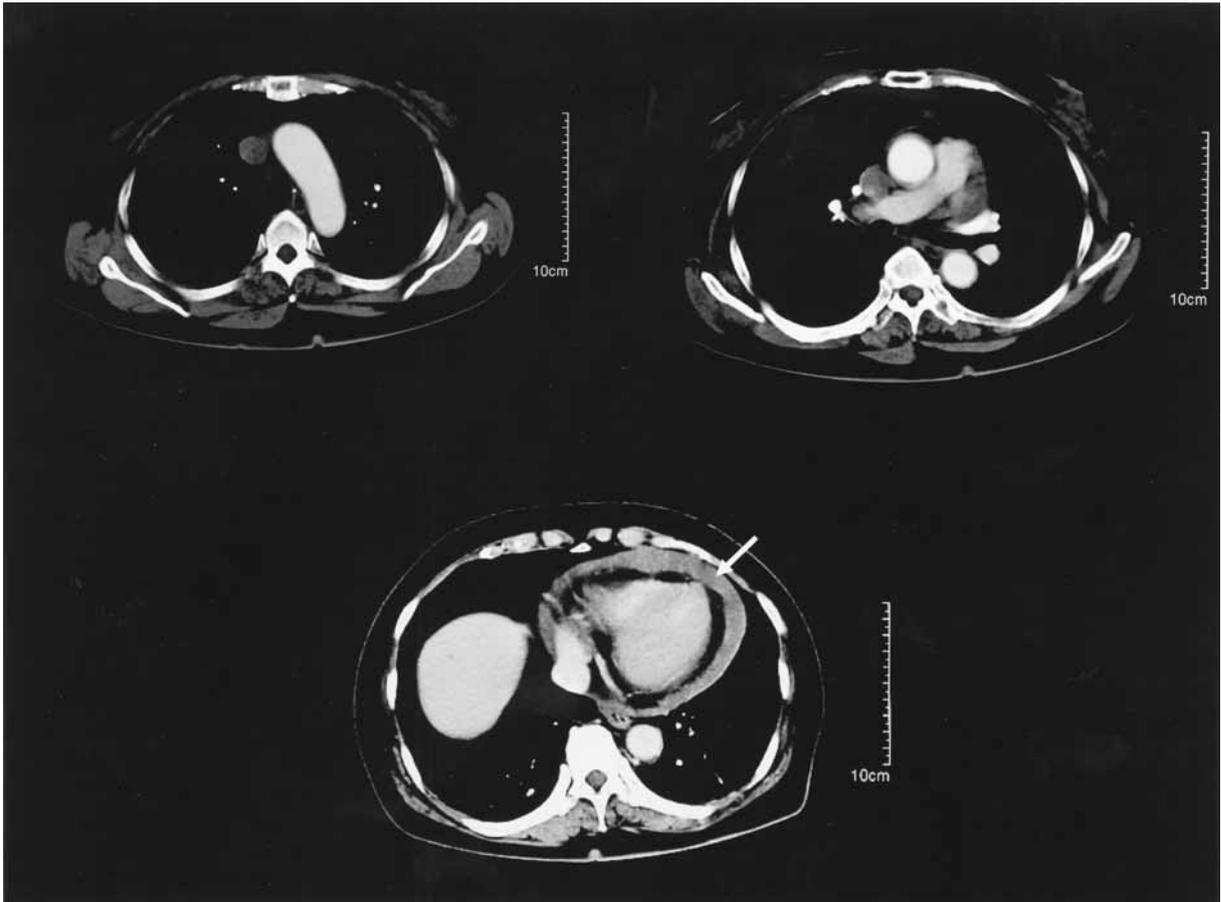

Although a cause of cardiac tamponade was unclear,

**Fig. 1.** Chest CT showed pericardial effusion (an arrow), but no aortic dissection.

we performed emergent surgical treatment without coronary angiography because she was pre-shock.

In operation, pericardial effusion was bloody and we found a hematoma and a dilated coronary arteriovenous fistula in area of left circumflex artery (LCx). The shape of this fistula was saccular, and it measured about 10 by 30 mm (Fig. 2). At this fistula, a bleeding point was identified. We put this fistula in between the felt strips like a sandwich and ligated on a beating heart.

On postoperative day one, coronary angiography showed the occlusion of a branch of LCx (Fig. 3), but the left ventricular wall motion and ECG was normal. She recovered uneventfully, and was discharged on the postoperative day 10.

## Discussion

Coronary artery fistula is an abnormal communication between an epicardial coronary artery and a cardiac cham-

ber or major vessel (vena cava, pulmonary artery etc.)<sup>1)</sup> and the most common congenital anomalies of the coronary arteries. Sometimes we find small coronary arteriovenous fistula in coronary angiography. Many patients with these anomalies remain asymptomatic, but some patients develop symptoms of congestive heart failure, infective endocarditis, myocardial ischemia, arrhythmia, or rupture of an aneurysmal fistula. Coronary steal, volume overload or an infection are the causes of these clinical manifestations.

Usually, the dilatation of fistula is common, and although 19% of this may become aneurysmal,<sup>2)</sup> the rupture of the aneurysm is very rare.

To the best of our knowledge, there are 12 cases of ruptured coronary arteriovenous fistula,<sup>3-14)</sup> excluding our case (Table 1). Surgical treatment was performed in twelve patients including ours. The prognosis was good in surgically treated patients.

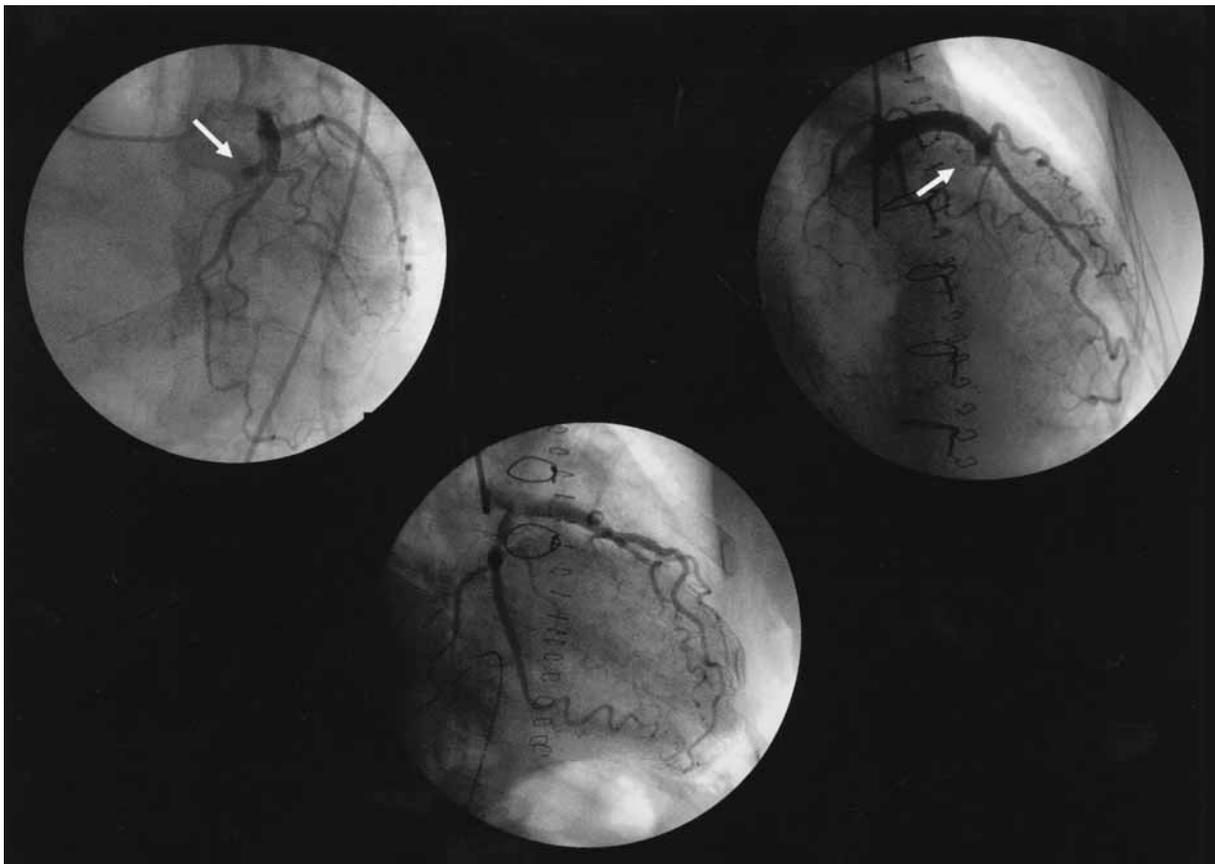

In this case, we took acute aortic dissection (Stanford

**Fig. 2.** In operation, a dilated coronary arteriovenous fistula that was saccular type, and measured about 10 by 30 mm was found in the area of the left circumflex artery (an arrow).

A type) into consideration, because of unconsciousness after chest and back pain, and cardiac tamponade at echocardiography on her arrival. Aortic dissection was not revealed at chest CT. Although the cause of cardiac tamponade was unclear, we performed emergency surgical treatment without coronary angiography because she was in a state of pre-shock. It is recommended to perform coronary angiography prior to surgery if patient is hemodynamically stable.

In order to permanently close the coronary fistula, surgical ligation and percutaneous closure are the currently available options. Transcatheter embolic occlusion of a coronary fistula have been successfully reported with a variety of materials, such as a covered stent, platinum coils, detachable balloons, double-umbrella devices and thrombogenic foams.<sup>15-17)</sup> Although transcatheter embolic occlusion is easier than surgical treatment, in a case of acute manifestation like this patient, we think it is necessary to perform an emergency surgical treatment.

**Fig. 3.** Coronary angiography showed total occlusion of a branch of the left circumflex artery (an arrow).
